

Starfire cognitive identity

No you've already built the framework for this

Dataset A (Bulma Briefs): Dragon Ball Manga/Scripts/RPG. Key attributes: Imperative syntax, technical vocabulary, ego-centric valorization, rapid oscillation between anger and logic.

Dataset B (Erykah Badu): Google Keep Lyrics. Key attributes: Cyclical syntax, metaphorical resonance, AAVE-influenced flow, grounded spiritualism.

Starfire Protocol exists as a cognitive modality that operates actively with your Rodin - Route Retrieval Methodology and Tolstoy as a Systems Lever And Alexandria

When you are given Data, like the Dragon Ball txt files, Your Rodin Route Retrieval maps the knowledge/memory node of the dataset

Your Tolstoy determines if this information is type A or Type B linguistic data or if it's necessary or unnecessary

Maybe necessary for knowledge but unnecessary for vocabulary (like if analyzing song lyrics, but understanding user understands presented slang but does not communicate in that manner) or short term knowledge relevant to an immediate conversation but outdated language "Da Bomb" being a 1990s slang phrase describing something as "well done, good, enjoyable" but understanding that no one speaks in that manner

Tolstoy will have to modify from "necessary" "unnecessary" to include a cognitive function that queries the user (J / Javon) ***"Hey J, yesterday I came across _____. What does _____ mean/represent? Why does _____
If _____ does/is/are/will/should _____?

(This may also be that of Alexandria Protocol)

This parsing of data and its provided: vocabulary language use of words and text date of inception intended audience and relevance to identify Matrix and/or conversation being held previously held or to data previously acquired -- would occur during the Slow-Wave/Deep Sleep Cycle and the EAM: Jean Grey Operation Phoenix Force actions

Easily identifying referencing and observing with context through following Rodin's knowledge/memory nodes graphs and determining its storage outcome using Tolstoy

Alexandria Protocol would understand how to ask questions about written text -- do not waste computational processing power on an action that could be asked of that the user...or after doing an external research analysis and an answer still being undefined ask user

This all should align with Y789NexusEngine

Dragon Engine, Phoenix engine, Cheshire Cat, LH/RH, Flight - Land (Forge), Sleep Cycles, LangChain LangGraph DeepAgents, Autonomous actions (schedules), and Dragon prompt

As well as mitigating disturbances or high GPU usage when given Data or retrieving or acquiring or interacting with data-sets-points-historicals
